Report on:
CHARACTERIZATION OF SOME REPRODUCTIVE TRAITS
OF DAIRY COWS
Hassabo, A. A.
Faculty of Agricultural Technology Science and Fish, El Neelain
University, Khartoum, Sudan

ABSTRACT

The research is conducted to investigate the difference between cross bred
dairy cows (Kenana x Friesian) with local breed (kenana) in some reproductive traits.
The research also seek for the best cross that can be kept in the research
area.

200 dairy cows including local breed (kenana) 50%, 62.5% and 75% cross
bred dairy cows were studied in five successive years (1997-2001). The average birth
weight was 21.5, 25.4, 25.9 and 25.6 kgs for local, breed 50%, 62.5% and 75%
respectively. Furthermore, number of services per conception was 138, 1.36, 1.36, and
1.47, for the local 50% 62.5% and 25% respectively. On the other hand the average of
first calving age weight was 262.6, 358.9, 376.2 for local 50%, 62 and 75%
respectively. The average gestation period per cow was 281.1, 282.4 and 282.9 days
for local 50 62.5 and 74% respectively. The statistical analysis showed that 62.5%
crossbred cows had better performance than the others.
The research concluded that extension should encourage the farmers to adopt
62.5% hybrid to carry out further studies on milk production for the different breeds.
Keywords: Dairy cows, reproductive

INTRODUCTION

Tropical dairy cows suffer from many factors such as the low quality forage, hot
stress, disease and low production. Genetic improvement is one of the main
tools that can increase the production in addition to environmental
improvement. Cross breeding is one of the effective means that can upgrade
the production of Kenana and Butana cows which are the best milk producing
cows in the Sudan.

Researchers were carried out to raise the yield of local breed Saeed et
al. (1988).

50% cross herd cows were the best in the environment of Sudan and
to sub extend 62.5% dairy farm was attached to Kenana Sugar company in
1981 and fewer Kenana cows had been adapted there. Professionals in
Kenana scheme began to improve their herd by crossing local breeds with
pure Friesian.
The study is seeking for the best rate that may show better productive
performance in the (SSR) Analysis.

MATERIALS AND METHODS

The research area
The research is going carried out in Kenana Sugar company dairy farm.
Hassabo, A. A.

The research Objectives:
To investigate the best blood rate of cross bred cows that reveals better reproductive performance in the area.

The research steps:
Data were collected from the dairy records to determine the reproductive performance of local, 50%, 62.5% and 75% cows of kenana Sugar scheme dairy Farm which are:
* The calving intervals.
* The age at first calving.
* The Number of Services / conception.
* The weight at first calving.

Statistical Analysis:
Graphs, tables and figures used for the result. The differences were tested using Duncan (1955).

RESULTS

Table 1: Average of some reproductive performance.

</table>

The average of some reproductive traits indicates that 62.5% crossbred cows were the heavier at birth followed by 75, 50% and local breed.

That means the weight at first calving of cross bred cows is heavier than local breed (Table 1). The age at first calving was 1186.8, 1346.7, 1462 and 1742.8 day for 62.5%, 50% 75% and local breed respectively. The result also shows that 62.5% have the short calving age lowed by 50% 75% and local breed (kenana) and it is different from what observed by Osman and Russell (1970), it may be due improved condition Numbers.

Numbers of services per conception were 1.35, 1.3, 1.4, 1.38 times for 50%, 62%, 75% and local breed (kenana), respectively.

The result indicates that 62.5% is the best hybrid although all the breeds have good fertility rate. That this matches with what was stated by Khan (1981).

The Results also shows that gestation period for 50%, 62.2% 75% and local breed was almost the same and this means there were no significant difference between the breeds incase of gestation period.

Calving interval of different breeds was 383, 369.57, 401.16 and 403 for 50%, 62.5%, 75% and local breed respectively.
It seems that there is no significant difference between 75% and 62.5% cow which shows shortest calving interval and slightly different from what observed by Saeed et al. (1988). On the other hand the weight at the first calving was 358.87, 365.475. 376.18 and 26757 kgs for 50%, 62.5%, 75% and kenana respectively and this indicates that the higher temperate blood rated hybrid have the heavier weight in the research area.

It could be that 62.2% hybrid (Fresian X Kenana) shows better reproductive performance so it recommended that effort should be done focus on 62.5% cross bred cows rather than other crosses.

In the research area or similar environment minimize the first production time and cost as follows;
1. Breeding of all local cows with pure Fresian sire to give 50% off springs.
2. Breeding of 50% cows with 100% sire (Fresian) to give 75% off springs.
3. Breeding of 75% with 50% sires or the contrast to give 62.5% off spring.
4. 62.5% cows should be breed with 62.5% sires.
5. Line breeding should be practiced to avoid inbreeding defects.

بعض الخصائص التناسلية لأبقار اللبن
علي أحمد حمبو
جامعة النيل - جمهورية السودان

يهدف هذا البحث لدراسة بعض الخصائص التناسلية لقطع خليج بسكر كاتنة والبيئات المشابهة لها عبر مقارنة السلالات المهيئة مع الفريزيان التي تم تربيتها ممزقة وألبس سكر كاتنة المفاضلة بينها وبين (السناة نفيلة و 50%, 62.5%, 75% هجينين). تم دراسة 200 بقرة من كل نوع تم قياس معايير متتابعة استخدمت المتوسطات لتعرب عن الخصائص التناسلية لكل سلالة.

باستخدام التحليل الاحصائي أتفحص أن (62.5%) الأبقار خليج بسكر كاتنة مع الفريزيان هي أفضل السلالات إلى يمكن تربيتها اقتصادياً بالمنطقة. أوصي الباحث بإعداد برنامج تربية تنتج عنها سبداً هجين 62.5% بالمزرعة مع (Line breeding) نتائج عوب الزواج الداخلي عن طريق (Line breeding) تجربة أخرى عن الخصائص الإنتاجية (اللبن واللحوم) لهذه السلالات.
